Programming in Haskell – Homework Assignment 5

UNIZG FER, 2014/2015

Handed out: November 2, 2014. Due: November 9, 2014 at 23:59

Note: Define each function with the exact name and the type specified. You can (and in most cases you should) define each function using a number of simpler functions. Provide a type signature above each function definition and comment the function above the type signature. Unless said otherwise, a function may not cause runtime errors and must be defined for all of its input values. Use the error function for cases in which a function should terminate with an error message. Problems marked with a star (\star) are optional.

Each problem is worth a certain number of points. The points are given at the beginning of each problem or subproblem (if they are scored independently). These points are scaled, together with a score for the in-class exercises, if any, to 10. Problems marked with a star (\star) are scored on top of the mandatory problems, before scaling. The score is capped at 10, but this allows for a perfect score even with problems remaining unsolved.

(1 pt) Define your own version of Data.List.Intercalate, called intercalate'.
 It must be implemented using explicit recursion.

```
intercalate' :: [a] -> [[a]] -> [a]
intercalate' xs yss == intercalate xs yss
```

2. (1 pt) Define the following functions that work with discrete random variables. You can assume the probabilities will always be valid $(0 \le p_i \le 1, \forall i \text{ and } \sum_{i=1}^{N} p_i = 1)$. The random variables are defined as follows:

```
type Probability = Double
type DiscreteRandVar = [(Int, Probability)]
x :: DiscreteRandVar
x = [(1, 0.2), (2, 0.4), (3, 0.1), (4, 0.2), (5, 0.05), (6, 0.05)]
```

(a) Define an explicitly recursive function mean and an accumulator-style recursive function mean' that calculate the mean (or expected value) of a discrete random variable, defined as $\sum_{i=1}^{N} x_i \cdot p_i$.

```
mean :: DiscreteRandVar -> Double mean' :: DiscreteRandVar -> Double mean x \Rightarrow 2.65 mean' x \Rightarrow 2.65
```

(b) Define an explicitly recursive function variance and an accumulator-style recursive function variance' that calculate the variance of a discrete random variable. Given the mean of the variable as μ_x , it is defined as $\sum_{i=1}^{N} (x_i - \mu_x)^2 \cdot p_i$.

```
variance :: DiscreteRandVar -> Double variance' :: DiscreteRandVar -> Double variance x \Rightarrow 1.9275 variance' x \Rightarrow 1.9275
```

(c) Define an explicitly recursive function probabilityFilter and an accumulatorstyle recursive function probabilityFilter' that take a probability and a random variable and return a list of values that have at least the given probability of appearing, in the same order in which they appear in the random variable definition.

```
probabilityFilter :: Probability -> DiscreteRandVar -> [Int] probabilityFilter' :: Probability -> DiscreteRandVar -> [Int] probabilityFilter 0 x \Rightarrow [1,2,3,4,5,6] probabilityFilter' 0 x \Rightarrow [1,2,3,4,5,6] probabilityFilter 0.2 x \Rightarrow [1,2,4] probabilityFilter' 0.2 x \Rightarrow [1,2,4]
```

- 3. (1 pt) Often we need to split up a list into smaller chunks. Define three functions to do just that.
 - (a) Define a function chunk that splits up a list xs into sublist of length n. If the length of xs is not a multiple of n, the last sublist will be shorter than n. Define the function using explicit recursion.

```
chunk :: Int -> [a] -> [[a]] chunk 2 "shadowless" \Rightarrow ["sh","ad","ow","le","ss"] chunk 4 "shadowless" \Rightarrow ["shad","owle","ss"] chunk 11 "shadowless" \Rightarrow ["shadowless"] chunk 0 "shadowless" \Rightarrow []
```

(b) Define a function chunkBy that splits up a list xs into sublists of lengths given in a list of indices is. If the lengths in is do not add up to the length of xs, the remaining part of xs will remain unchunked. Define the function using explicit recursion.

```
chunkBy :: [Int] -> [a] -> [[a]] chunkBy [1,2,3] "shadowless" \Rightarrow ["s","ha","dow"] chunkBy [11,2] "shadowless" \Rightarrow ["shadowless"] chunkBy [3,0,3,4] "shadowless" \Rightarrow ["sha","dow","less"] chunkBy [] "shadowless" \Rightarrow []
```

(c) Define a function chunkInto that splits up a list xs into n sublists of equal length. If the length of xs is not divisible by n, chunk the remainder into the last sublist. Define the function using explicit recursion.

```
\begin{array}{lll} \mbox{chunkInto} & :: & \mbox{Int} & > & \mbox{[a]} & \mbox{chunkInto} & 5 & \mbox{"shadowless"} & \Rightarrow & \mbox{["sh","ad","ow","le","ss"]} \\ \mbox{chunkInto} & 3 & \mbox{"shadowless"} & \Rightarrow & \mbox{["sha","dow","less"]} \\ \mbox{chunkInto} & 1 & \mbox{"shadowless"} & \Rightarrow & \mbox{["shadowless"]} \\ \mbox{chunkInto} & 0 & \mbox{"shadowless"} & \Rightarrow & \mbox{[]} \\ \mbox{chunkInto} & 11 & \mbox{"shadowless"} & \Rightarrow & \mbox{[]} \\ \mbox{chunkInto} & 11 & \mbox{"shadowless"} & \Rightarrow & \mbox{["s","h","a","d","o","w","l","e","s","s"]} \\ \end{array}
```

4. (1 pt) Define a function rpnCalc that takes a mathematical expression written in Reverse Polish notation and calculates its result. The expression is limited to 1-digit positive integers and operators +,-,*,/, and ^ where / is integer division and ^ is exponentiation.

```
rpnCalc :: String \rightarrow Int rpnCalc "32-1+" \Rightarrow 2
```

```
rpnCalc "321-+5-" \Rightarrow -1 rpnCalc "42^2/" \Rightarrow 8 rpnCalc "35*2/" \Rightarrow 7 rpnCalc "35*7-3^43*/" \Rightarrow 42 rpnCalc "" \Rightarrow 0 rpnCalc "33++" \Rightarrow error "Invalid RPN expression"
```

- 5. (1 pt)
 - (a) Define a function gcd' that calculates the greatest common divisor of two integers, using explicit recursion and the Euclidean algorithm.

```
gcd' :: Int -> Int -> Int gcd' 75 125 \Rightarrow 25 gcd' 1592 368 \Rightarrow 8 gcd' 17 4 \Rightarrow 1 gcd' (-153) 24 \Rightarrow 3 gcd' (-2541) (-1134) \Rightarrow 21 gcd' 15 0 \Rightarrow 15
```

(b) Define a function gcdAll that calculates the greatest common divisor of an arbitrary number of integers given in a list.

```
gcdAll :: [Int] \rightarrow Int gcdAll [3,15] \Rightarrow 3 gcdAll [21,49,14,(-14)] \Rightarrow 7 gcdAll [52] \Rightarrow 52 gcdAll [7060, 16944, 19768] \Rightarrow 1412 gcdAll [] \Rightarrow error "Cannot compute gcd of an empty list"
```

(c) Define a function extendedGcd which uses the extended Euclidean algorithm to calculate the Bezout coefficients along with the gcd. Given the constants a and b, it calculates x, y and gcd(a,b) that satisfy the expression a*x + b*y = gcd(a,b), returning them in a tuple, in that order.

```
extendedGcd :: Int \rightarrow Int \rightarrow (Int,Int,Int)
extendedGcd 240 46 \Rightarrow (-9,47,2)
extendedGcd 314 159 \Rightarrow (-40,79,1)
extendedGcd 1245 (-1603) \Rightarrow (300,233,1)
```

6. (1 pt) Implement a function isBipartite that takes an unweighted graph represented as an adjacency list and checks whether the given graph is a bipartite graph. A graph is considered bipartite if its vertices can be split into two disjoint sets such that there is no edge which connects two vertices from the same set.

```
type AdjacencyList = [Int]

type Graph = [AdjacencyList]

isBipartite :: Graph -> Bool

isBipartite [[2],[1]] \Rightarrow True

isBipartite [[4,5,6],[4,5,6],[4,5,6],[1,2,3],[1,2,3]] \Rightarrow True

isBipartite [[2,3],[3,1],[1,2]] \Rightarrow False
```

7. (1.5 pts) Define a function permutations' that, given a list, returns a list of all its permutations. Implement it using explicit recursion. The ordering of the list of permutations is irrelevant!

```
permutations' :: [a] -> [[a]] permutations' "hi" \Rightarrow ["hi", "ih"] permutations' [1,2,3] \Rightarrow [[1,2,3],[2,1,3],[3,2,1],[2,3,1],[3,1,2],[1,3,2]] permutations' [] \Rightarrow [[]]
```

- 8.* (2 pts) Imagine a group of differently—sized frogs living in a swamp with only three lily pads numbered from 1 to 3. Every morning, frogs meet at the first lily pad and spend all day trying to reach the third one, thereby abiding the following rules:
 - A frog cannot jump between the first and the third lily pad as they are too far apart;
 - A frog can jump from a lily pad only if it is the smallest frog on that lily pad;
 - A frog can jump on a lily pad only if it is smaller than all frogs on that lily pad.

Your job is to define a function frogJumps that, given a number of frogs n, computes the minimal number of jumps necessary for all n frogs to reach the third lily pad.

```
frogJumps :: Int -> Integer frogJumps 1 \Rightarrow 2 frogJumps 2 \Rightarrow 8 frogJumps 5 \Rightarrow 242 frogJumps 20 \Rightarrow 3486784400
```
